Preface

IMPORTANT: This document focuses at the moment on 1st and 2nd generation devices (models before the Game Boy Color), and some hardware details are very different in later generations.

Be very careful if you make assumptions about later generation devices based on this document!

How to read this document

This is something that hasn't been verified, but would make a lot of sense.

This explains some caveat about this documentation that you should know.

This is a warning about something.

0.1 Formatting of numbers

When a single bit is discussed in isolation, the value looks like this: 0, 1.

Binary numbers are prefixed with 0b like this: 0b0101101, 0b11011, 0b00000000. Values are prefixed with zeroes when necessary, so the total number of digits always matches the number of digits in the value.

Hexadecimal numbers are prefixed with 0x like this: 0x1234, 0xDEADBEEF, 0xFF04. Values are prefixed with zeroes when necessary, so the total number of characters always matches the number of nibbles in the value.

Examples:

	4-bit	8-bit	16-bit
Binary	0b0101	0b10100101	0b0000101010100101
Hexadecimal	0x5	0xA5	0x0AA5

0.2 Register definitions

Register 0.1: 0x1234 - This is a hardware register definition

R/W-0	R/W-1	U-1	R-0	R-1	R-x	W-1	U-0
VALUE <1:0>		–	BIGVAL <7:5>			FLAG	–
bit 7	6	5	4	3	2	1	bit 0

Top row legend:

R	Bit can be read.
W	Bit can be written. If the bit cannot be read, reading returns a constant value defined in the bit list of the register in question.
U	Unimplemented bit. Writing has no effect, and reading returns a constant value defined in the bit list of the register in question.
-n	Value after system reset: 0, 1, or x.
1	Bit is set.
0	Bit is cleared.
x	Bit is unknown (e.g. depends on external things such as user input).

Middle row legend:

VALUE <1:0>	Bits 1 and 0 of VALUE
–	Unimplemented bit
BIGVAL <7:5>	Bits 7, 6, 5 of BIGVAL
FLAG	Single-bit value FLAG

In this example:

- After system reset, VALUE is 0b01, BIGVAL is either 0b010 or 0b011, FLAG is 0b1.
- Bits 5 and 0 are unimplemented. Bit 5 always returns 1, and bit 0 always returns 0.
- Both bits of VALUE can be read and written. When this register is written, bit 7 of the written value goes to bit 1 of VALUE.
- FLAG can only be written to, so reads return a value that is defined elsewhere.
- BIGVAL cannot be written to. Only bits 5-7 of BIGVAL are defined here, so look elsewhere for the low bits 0-4.

Part I

Sharp SM83 CPU core

Chapter 1

CPU core timing

1.1 Fetch/execute overlap

Sharp SM83 uses a microprocessor design technique known as *fetch/execute overlap* to improve CPU performance by doing opcode fetches in parallel with instruction execution whenever possible. Since the CPU can only perform one memory access per M-cycle, it is worth it to try to do memory operations as soon as possible. Also, when doing a memory read, the CPU cannot use the data during the same M-cycle so the true minimum effective duration of instructions is 2 machine cycles, not 1 machine cycle.

Every instruction needs one machine cycle for the fetch stage, and at least one machine cycle for the decode/execute stage. However, the fetch stage of an instruction always overlaps with the last machine cycle of the execute stage of the previous instruction. The overlapping execute stage cycle may still do some work (e.g. ALU operation and/or register writeback) but memory access is reserved for the fetch stage of the next instruction.

Since all instructions effectively last one machine cycle longer, fetch/execute overlap is usually ignored in documentation intended for programmers. It is much easier to think of a program as a sequence of non-overlapping instructions and consider only the execute stages when calculating instruction durations. However, when emulating a SM83 CPU core, understanding and emulating the overlap can be useful.

Sharp SM831x is a family of single-chip SoCs from Sharp that use the SM83 CPU core, and their datasheet [5] includes a description of fetch/execute overlap. However, the description is not completely correct and can in fact be misleading. For example, the timing diagram includes an instruction that does not involve opcode fetch at all, and memory operations for two instructions are shown to happen at the same time, which is not possible.

Fetch/execute overlap timing example

Let's assume the CPU is executing a program that starts from the address 0x1000 and contains the following instructions:

0x1000: INC A

0x1001: LDH (n), A

0x1003: RST 0x08

0x0008: NOP

The following timing diagram shows all memory operations done by the CPU, and the fetch and execute stages of each instruction:

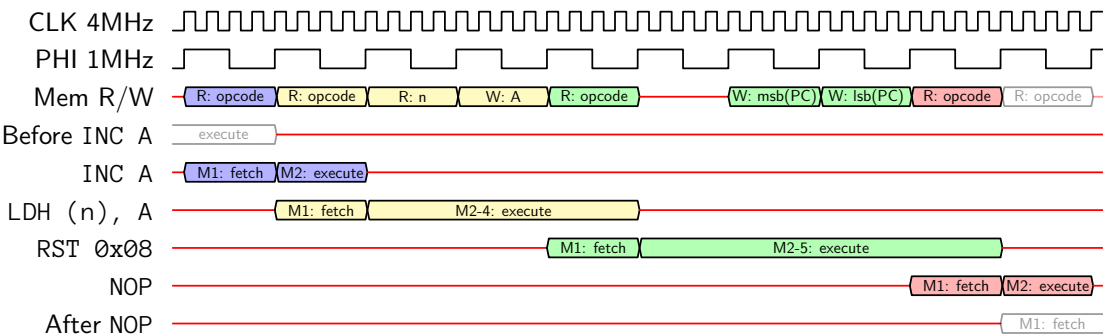

Figure 1.1: Fetch/execute overlap example

Chapter 2

Sharp SM83 instruction set

2.1 8-bit load instructions

8-bit load instructions transfer one byte of data between two 8-bit registers, or between one 8-bit register and location in memory.

LD r, r'

Load to the 8-bit register r, data from the 8-bit register r'.

Opcode 0b01xxxyyy / various

Length 1 byte

Duration 1 machine cycle

Flags -

Pseudocode

```
opcode = read(PC++)  
# example: LD B, C  
if opcode == 0x41:  
    B = C
```

LD r, n

Load to the 8-bit register r, the immediate data n.

Opcode 0b00xxx110 / various + n

Length 2 byte

Duration 2 machine cycles

Flags -

Pseudocode

```
opcode = read(PC++)  
# example: LD B, n  
if opcode == 0x06:  
    B = read(PC++)
```

LD r, (HL)

Load to the 8-bit register *r*, data from the absolute address specified by the 16-bit register HL.

Opcode 0b01xxx110/variou

Length 1 byte

Duration 2 machine cycles

Flags -

Pseudocode

```
opcode = read(PC++)
# example: LD B, (HL)
if opcode == 0x46:
    B = read(HL)
```

LD (HL), r

Load to the absolute address specified by the 16-bit register HL, data from the 8-bit register *r*.

Opcode 0b01110xxx/variou

Length 1 byte

Duration 2 machine cycles

Flags -

Pseudocode

```
opcode = read(PC++)
# example: LD (HL), B
if opcode == 0x70:
    write(HL, B)
```

LD (HL), n

Load to the absolute address specified by the 16-bit register HL, the immediate data *n*.

Opcode 0b00110110/0x36 + *n*

Length 2 bytes

Duration 3 machine cycles

Flags -

Pseudocode

```
opcode = read(PC++)
if opcode == 0x36:
    n = read(PC++)
    write(HL, n)
```

LD A, (BC)

Load to the 8-bit A register, data from the absolute address specified by the 16-bit register BC.

Opcode 0b00001010/0x0A

Length 1 byte

Duration 2 machine cycles

Flags -

Pseudocode

```
opcode = read(PC++)
if opcode == 0x0A:
    A = read(BC)
```

LD A, (DE)

Load to the 8-bit A register, data from the absolute address specified by the 16-bit register DE.

Opcode 0b00011010/0x1A

Length 1 byte

Duration 2 machine cycles

Flags -

Pseudocode

```
opcode = read(PC++)
if opcode == 0x1A:
    A = read(DE)
```

LD (BC), a

Load to the absolute address specified by the 16-bit register BC, data from the 8-bit A register.

Opcode 0b00000010/0x02

Length 1 byte

Duration 2 machine cycles

Flags -

Pseudocode

```
opcode = read(PC++)
if opcode == 0x02:
    write(BC, A)
```

LD (DE), a

Load to the absolute address specified by the 16-bit register DE, data from the 8-bit A register.

Opcode 0b00010010/0x12

Length 1 byte

Duration 2 machine cycles

Flags -

Pseudocode

```
opcode = read(PC++)
if opcode == 0x12:
    write(DE, A)
```

LD A, (nn)

Load to the 8-bit A register, data from the absolute address specified by the 16-bit operand nn.

Opcode 0b11111010/0xFA + LSB of nn + MSB of nn

Length 3 bytes

Duration 4 machine cycles

Flags -

Pseudocode

```
opcode = read(PC++)
if opcode == 0xFA:
    nn = unsigned_16(lsb=read(PC++), msb=read(PC++))
    A = read(nn)
```

LD (nn), A

Load to the absolute address specified by the 16-bit operand nn, data from the 8-bit A register.

Opcode 0b11101010/0xEA + LSB of nn + MSB of nn

Length 3 bytes

Duration 4 machine cycles

Flags -

Pseudocode

```
opcode = read(PC++)
if opcode == 0xEA:
    nn = unsigned_16(lsb=read(PC++), msb=read(PC++))
    write(nn, A)
```

LDH A, (C)

Load to the 8-bit A register, data from the address specified by the 8-bit C register. The full 16-bit absolute address is obtained by setting the most significant byte to 0xFF and the least significant byte to the value of C, so the possible range is 0xFF00–0xFFFF.

Opcode 0b11110010/0xF2

Length 1 bytes

Duration 2 machine cycles

Flags -

Pseudocode

```
opcode = read(PC++)
if opcode == 0xF2:
    A = read(unsigned_16(lsb=C, msb=0xFF))
```

LDH (C), A

Load to the address specified by the 8-bit C register, data from the 8-bit A register. The full 16-bit absolute address is obtained by setting the most significant byte to 0xFF and the least significant byte to the value of C, so the possible range is 0xFF00–0xFFFF.

Opcode 0b11100010/0xE2

Length 1 bytes

Duration 2 machine cycles

Flags -

Pseudocode

```
opcode = read(PC++)
if opcode == 0xE2:
    write(unsigned_16(lsb=C, msb=0xFF), A)
```

LDH A, (n)

Load to the 8-bit A register, data from the address specified by the 8-bit immediate data n. The full 16-bit absolute address is obtained by setting the most significant byte to 0xFF and the least significant byte to the value of n, so the possible range is 0xFF00–0xFFFF.

Opcode 0b11110000/0xF0

Length 2 bytes

Duration 3 machine cycles

Flags -

Pseudocode

```
opcode = read(PC++)
if opcode == 0xF0:
    n = read(PC++)
    A = read(unsigned_16(lsb=n, msb=0xFF))
```

LDH (n), A

Load to the address specified by the 8-bit immediate data *n*, data from the 8-bit A register. The full 16-bit absolute address is obtained by setting the most significant byte to 0xFF and the least significant byte to the value of *n*, so the possible range is 0xFF00–0xFFFF.

Opcode 0b11100000/0xE0

Length 2 bytes

Duration 3 machine cycles

Flags -

Pseudocode

```
opcode = read(PC++)
if opcode == 0xE0:
    n = read(PC++)
    write(unsigned_16(lsb=n, msb=0xFF), A)
```

LD A, (HL-)

Load to the 8-bit A register, data from the absolute address specified by the 16-bit register HL. The value of HL is decremented after the memory read.

Opcode 0b00111010/0x3A

Length 1 bytes

Duration 2 machine cycles

Flags -

Pseudocode

```
opcode = read(PC++)
if opcode == 0x3A:
    A = read(HL--)
```

LD (HL-), A

Load to the absolute address specified by the 16-bit register HL, data from the 8-bit A register. The value of HL is decremented after the memory write.

Opcode 0b00110010/0x32

Length 1 bytes

Duration 2 machine cycles

Flags -

Pseudocode

```
opcode = read(PC++)
if opcode == 0x32:
    write(HL--, A)
```

LD A, (HL+)

Load to the 8-bit A register, data from the absolute address specified by the 16-bit register HL. The value of HL is incremented after the memory read.

Opcode 0b00101010/0x2A

Length 1 bytes

Duration 2 machine cycles

Flags -

Pseudocode

```
opcode = read(PC++)
if opcode == 0x2A:
    A = read(HL++)
```

LD (HL+), A

Load to the absolute address specified by the 16-bit register HL, data from the 8-bit A register. The value of HL is incremented after the memory write.

Opcode 0b00100010/0x22

Length 1 bytes

Duration 2 machine cycles

Flags -

Pseudocode

```
opcode = read(PC++)
if opcode == 0x22:
    write(HL++, A)
```

2.2 16-bit load instructions

16-bit load instructions transfer two bytes of data between two 16-bit registers, or between one 16-bit register and two sequential locations in memory.

LD rr, nn

Load to the 16-bit register rr, the immediate 16-bit data nn.

Opcode 0b00xx0001 / various + LSB of nn + MSB of nn

Length 3 byte

Duration 3 machine cycles

Flags -

Pseudocode

```
opcode = read(PC++)
# example: LD BC, nn
if opcode == 0x01:
    nn = unsigned_16(lsb=read(PC++), msb=read(PC++))
    BC = nn
```

LD (nn), SP

Load to the absolute address specified by the 16-bit operand nn, data from the 16-bit SP register.

Opcode 0b00001000/0x08 + LSB of nn + MSB of nn

Length 3 byte

Duration 5 machine cycles

Flags -

Pseudocode

```
opcode = read(PC++)
if opcode == 0x08:
    nn = unsigned_16(lsb=read(PC++), msb=read(PC++))
    write(nn, lsb(SP))
    write(nn+1, msb(SP))
```

LD SP, HL

Load to the 16-bit SP register, data from the 16-bit HL register.

Opcode 0b11111001/0xF9

Length 1 byte

Duration 2 machine cycles

Flags -

Pseudocode

```
opcode = read(PC++)
if opcode == 0xF9:
    SP = HL
```

PUSH rr

Push to the stack memory, data from the 16-bit register rr.

Opcode 0b11xx0101/ various

Length 1 byte

Duration 4 machine cycles

Flags -

Pseudocode

```
opcode = read(PC++)
# example: PUSH BC
if opcode == 0xC5:
    SP--
    write(SP--, msb(BC))
    write(SP, lsb(BC))
```

POP rr

Pops to the 16-bit register rr, data from the stack memory.

This instruction does not do calculations that affect flags, but POP AF completely replaces the F register value, so all flags are changed based on the 8-bit data that is read from memory.

Opcode 0b11xx0001 / various

Length 1 byte

Duration 3 machine cycles

Flags see the instruction description

Pseudocode

```
opcode = read(PC++)
# example: POP BC
if opcode == 0xC1:
    BC = unsigned_16(lsb=read(SP++), msb=read(SP++))
```

2.3 8-bit arithmetic instructions

2.4 16-bit arithmetic instructions

2.5 Rotate, shift, and bit operation instructions

2.6 Control flow instructions

JP nn

Unconditional jump to the absolute address specified by the 16-bit operand nn.

Opcode + data 0b11000011 / 0xC3 + LSB of nn + MSB of nn

Length 3 bytes

Duration 4 machine cycles

Flags -

Pseudocode

```
opcode = read(PC++)
if opcode == 0xC3:
    nn = unsigned_16(lsb=read(PC++), msb=read(PC++))
    PC = nn
```

JP HL

Unconditional jump to the absolute address specified by the 16-bit register HL.

Opcode 0b11101001/0xE9

Length 1 byte

Duration 1 machine cycle

Flags -

Pseudocode

```
opcode = read(PC++)
if opcode == 0xE9:
    PC = HL
```

In some documentation this instruction is written as JP [HL]. This is very misleading, since brackets are usually used to indicate a memory read, and this instruction simply copies the value of HL to PC.

JP cc, nn

Conditional jump to the absolute address specified by the 16-bit operand nn, depending on the condition cc.

Note that the operand (absolute address) is read even when the condition is false!

Opcode + data 0b110cc010/various + LSB of nn + MSB of nn

Length 3 bytes

Duration 3 machine cycles (cc=false), or 4 machine cycles (cc=true)

Flags -

Pseudocode

```
opcode = read(PC++)
if opcode in [0xC2, 0xD2, 0xCA, 0xDA]:
    nn = unsigned_16(lsb=read(PC++), msb=read(PC++))
    if F.check_condition(cc):
        PC = nn
```

JR e

Unconditional jump to the relative address specified by the signed 8-bit operand e.

Opcode + data 0b00011000/0x18 + offset e

Length 2 bytes

Duration 3 machine cycles

Flags

-

Timing**Pseudocode**

```
opcode = read(PC++)
if opcode == 0x18:
    e = signed_8(read(PC++))
    PC = PC + e
```

JR cc, e

Conditional jump to the relative address specified by the signed 8-bit operand e, depending on the condition cc.

Note that the operand (relative address offset) is read even when the condition is false!

Opcode + data 0b001cc000/ various + offset e

Length 2 bytes

Duration 2 machine cycles (cc=false), or 3 machine cycles (cc=true)

Flags

-

Timing (cc=false)**Timing (cc=true)****Pseudocode**

```
opcode = read(PC++)
if opcode in [0x20, 0x30, 0x28, 0x38]:
    e = signed_8(read(PC++))
    if F.check_condition(cc):
        PC = PC + e
```

CALL nn

Unconditional function call to the absolute address specified by the 16-bit operand nn.

Opcode + data 0b11001101/0xCD + LSB of nn + MSB of nn

Length 3 bytes

Duration 6 machine cycles

Flags

-

Timing**Pseudocode**

```
opcode = read(PC++)
if opcode == 0xCD:
    nn = unsigned_16(lsb=read(PC++), msb=read(PC++))
    SP--
    write(SP--, msb(PC))
    write(SP, lsb(PC))
    PC = nn
```

CALL cc, nn

Conditional function call to the absolute address specified by the 16-bit operand nn, depending on the condition cc.

Note that the operand (absolute address) is read even when the condition is false!

Opcode + data	0b110cc100/ various + LSB of nn + MSB of nn
Length	3 bytes
Duration	3 machine cycles (cc=false), or 6 machine cycles (cc=true)
Flags	-

Pseudocode

```

opcode = read(PC++)
if opcode in [0xC4, 0xD4, 0xCC, 0xDC]:
    nn = unsigned_16(lsb=read(PC++), msb=read(PC++))
    if F.check_condition(cc):
        SP--
        write(SP--, msb(PC))
        write(SP, lsb(PC))
        PC = nn

```

RET

Unconditional return from a function.

Opcode	0b11001001/0xC9
Length	1 byte
Duration	4 machine cycles
Flags	-

Pseudocode

```

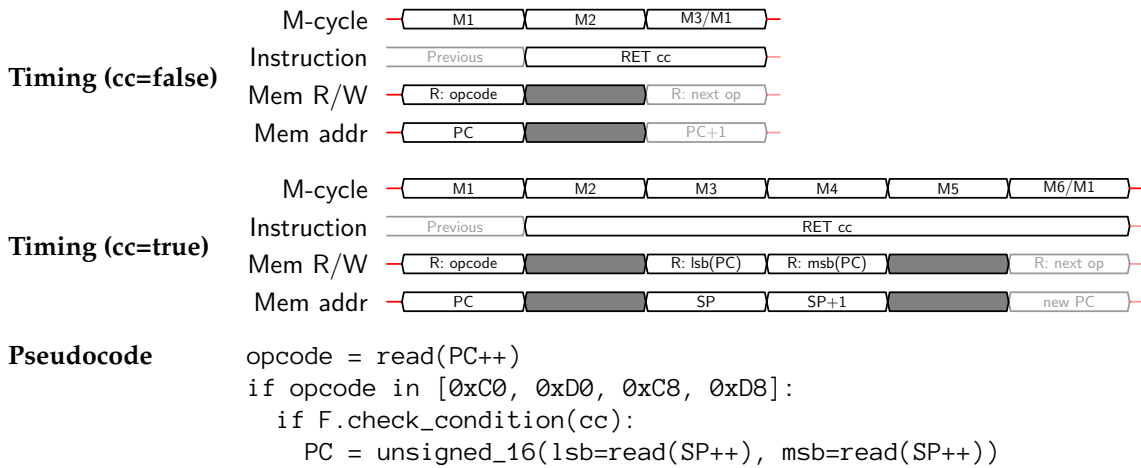

opcode = read(PC++)
if opcode == 0xC9:
    PC = unsigned_16(lsb=read(SP++), msb=read(SP++))

```

RET cc

Conditional return from a function, depending on the condition cc.

Opcode	0b110cc000/ various
Length	1 byte
Duration	2 machine cycles (cc=false), or 5 machine cycles (cc=true)
Flags	-

RETI

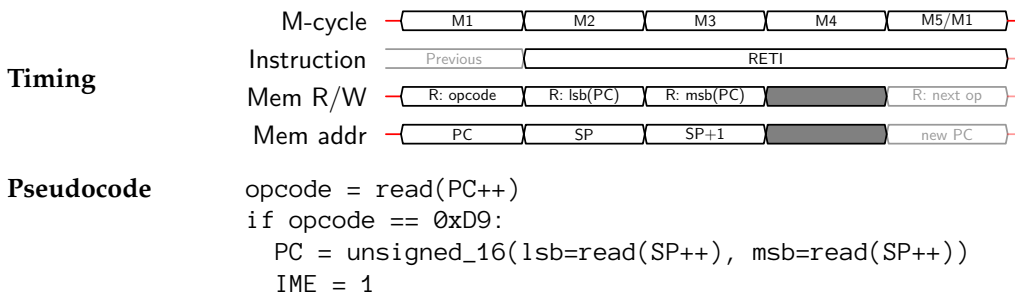

Unconditional return from a function. Also enables interrupts by setting IME=1.

Opcode 0b11011001/0xD9

Length 1 byte

Duration 4 machine cycles

Flags -

RST n

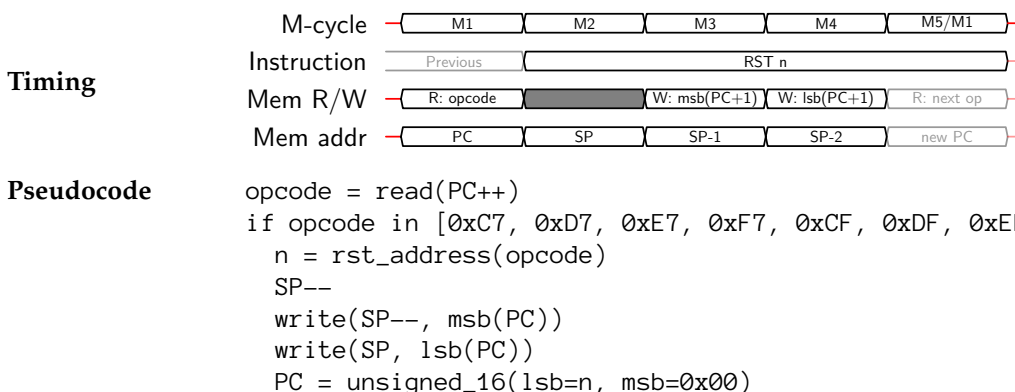

Unconditional function call to the absolute fixed address defined by the opcode.

Opcode 0b11xxx111/various

Length 1 byte

Duration 4 machine cycles

Flags -

2.7 Miscellaneous instructions

HALT

STOP

DI

Disables interrupt handling by setting IME=0 and cancelling any scheduled effects of the EI instruction if any.

Opcode 0b11110011/0xF3

Length 1 byte

Duration 1 machine cycle

Flags -

Pseudocode

```
opcode = read(PC++)
if opcode == 0xF3:
    IME = 0
```

EI

Schedules interrupt handling to be enabled after the next machine cycle.

Opcode 0b11111011/0xFB

Length 1 byte

Duration 1 machine cycle (+ 1 machine cycle for the effect)

Flags -

Pseudocode

```
opcode = read(PC++)
if opcode == 0xFB:
    IME_scheduled = true
```

CCF

Flips the carry flag, and clears the N and H flags.

Opcode 0b00111111/0x3F

Length 1 byte

Duration 1 machine cycle

Flags N = 0, H = 0, C = ★

Pseudocode

```
opcode = read(PC++)
if opcode == 0x3F:
    flags.N = 0
    flags.H = 0
    flags.C = ~flags.C
```

SCF

Sets the carry flag, and clears the N and H flags.

Opcode 0b00110111/0x37

Length 1 byte

Duration 1 machine cycle

Flags N = 0, H = 0, C = 1

Pseudocode

```
opcode = read(PC++)
if opcode == 0x37:
    flags.N = 0
    flags.H = 0
    flags.C = 1
```

NOP

No-operation. This instruction doesn't do anything, but can be used to add a delay of one machine cycle and increment PC by one.

Opcode 0b00000000/0x00

Length 1 byte

Duration 1 machine cycle

Flags -

Pseudocode

```
opcode = read(PC++)
if opcode == 0x00:
    // nothing
```

DAA

Opcode 0b00100111/0x27

Length 1 byte

Duration 1 machine cycle

Part II

Game Boy SoC peripherals and features

Chapter 3

Boot ROM

The Game Boy SoC includes a small embedded boot ROM, which can be mapped to the 0x0000–0x00FF memory area. While mapped, all reads from this area are handled by the boot ROM instead of the external cartridge, and all writes to this area are ignored and cannot be seen by external hardware (e.g. the cartridge MBC).

The boot ROM is enabled by default, so when the system exits the reset state and the CPU starts execution from address 0x0000, it executes the boot ROM instead of instructions from the cartridge ROM. The boot ROM is responsible for showing the initial logo, and checking that a valid cartridge is inserted into the system. If the cartridge is valid, the boot ROM unmaps itself before execution of the cartridge ROM starts at 0x0100. The cartridge ROM has no chance of executing any instructions before the boot ROM is unmapped, which prevents the boot ROM from being read byte by byte in normal conditions.

Don't confuse the boot ROM with the additional SNES ROM in SGB/SGB2 that is executed by the SNES CPU.

Register 3.1: 0xFF50 - BOOT - Boot ROM lock register

U-1	U-1	U-1	U-1	U-1	U-1	U-1	R/W-0
–	–	–	–	–	–	–	BOOT_OFF
bit 7	6	5	4	3	2	1	bit 0

bit 7-1 **Unimplemented:** Read as 1

bit 0 **BOOT_OFF:** Boot ROM lock bit

0b1= Boot ROM is disabled and 0x0000–0x00FF works normally.

0b0= Boot ROM is active and intercepts accesses to 0x0000–0x00FF.

BOOT_OFF can only transition from 0b0 to 0b1, so once 0b1 has been written, the boot ROM is permanently disabled until the next system reset. Writing 0b0 when BOOT_OFF is 0b0 has no effect and doesn't lock the boot ROM.

The 1-bit BOOT register controls mapping of the boot ROM. Once 1 has been written to it to unmap the boot ROM, it can only be mapped again by resetting the system.

3.1 Boot ROM types

Table 3.1: Summary of boot ROM file hashes

Type	CRC32	MD5	SHA1
DMG	59c8598e	32fbbd84168d3482956eb3c5051637f5	4ed31ec6b0b175bb109c0eb5fd3d193da82339f

DMG boot ROM

The most common boot ROM is the DMG boot ROM used in almost all original Game Boy units. If a valid cartridge is inserted, the boot ROM scrolls a logo to the center of the screen, and plays a "di-ding" sound recognizable by most people who have used Game Boy consoles.

This boot ROM was originally dumped by neviksti in 2003 by decapping the Game Boy SoC and visually inspecting every single bit.

MGB boot ROM

This boot ROM was originally dumped by Bennvenn in 2014 by using a simple clock glitching method that only requires one wire.

SGB boot ROM

This boot ROM was originally dumped by Costis Sideris in 2009 by using an FPGA-based clock glitching method [6].

SGB2 boot ROM

This boot ROM was originally dumped by gekkio in 2015 by using a Teensy 3.1 -based clock glitching method [2].

Early DMG boot ROM

Very early original Game Boy units released in Japan (often called "DMG0") included the launch version "DMG-CPU" SoC chip, which used a different boot ROM than later units.

This boot ROM was originally dumped by gekkio in 2016 by using a clock glitching method invented by BennVenn.

Chapter 4

DMA (Direct Memory Access)

4.1 Object Attribute Memory (OAM) DMA

OAM DMA is a high-throughput mechanism for copying data to the OAM area (a.k.a. Object Attribute Memory, a.k.a. sprite memory). It can copy one byte per machine cycle without involving the CPU at all, which is much faster than the fastest possible memcpy routine that can be written with the SM83 instruction set. However, a transfer cannot be cancelled and the transfer length cannot be controlled, so the DMA transfer always updates the entire OAM area (= 160 bytes) even if you actually want to just update the first couple of bytes.

The Game Boy CPU chip contains a DMA controller that coordinates transfers between a *source area* and the *OAM area* independently of the CPU. While a transfer is in progress, it takes control of the source bus and the OAM area, so some precaution is needed with memory accesses (including instruction fetches) to avoid OAM DMA bus conflicts. OAM DMA uses a different address decoding scheme than normal memory accesses, so the source bus is always either the external bus or the video RAM bus, and the contents normally visible to the CPU in the 0xFE00–0xFFFF address range cannot be used as a source for OAM DMA transfers.

The upper 8 bits of the OAM DMA source address are stored in the DMA register, while the lower 8 bits used by both the source and target address are stored in the DMA controller and are not accessible directly. A transfer always begins with 0x00 in the lower bits and copies exactly 160 bytes, so the lower bits are never in the 0xA0–0xFF range.

Writing to the DMA register updates the upper bits of the DMA source address and also triggers an OAM DMA transfer request, although the DMA transfer does not begin immediately.

Register 4.1: 0xFF46 - DMA - OAM DMA control register

R/W-x	R/W-x	R/W-x	R/W-x	R/W-x	R/W-x	R/W-x	R/W-x
DMA<7:0>							
bit 7	6	5	4	3	2	1	bit 0

bit 0 **DMA<7:0>:** OAM DMA source address

Specifies the top 8 bits of the OAM DMA source address.

Writing to this register requests an OAM DMA transfer, but it's just a request and the actual DMA transfer starts with a delay.

Reading this register returns the value that was previously written to the register. The stored value is not cleared on reset, so the initial value before the first write is unknown and should not be relied on.

Avoid writing 0xE0–0xFF to the DMA register, because some poorly designed flash carts can trigger bus conflicts or other dangerous behaviour.

OAM DMA address decoding

The OAM DMA controller uses a simplified address decoding scheme, which leads to some addresses being unusable as source addresses. Unlike normal memory accesses, OAM DMA transfers interpret all accesses in the 0xA000–0xFFFF range as external RAM transfers. For example, if the OAM DMA wants to read 0xFF00,

it will output `0xFF00` on the external address bus and will assert the external RAM chip select signal. The P1 register which is normally at `0xFF00` is not involved at all, because OAM DMA address decoding only uses the external bus and the video RAM bus. Instead, the resulting behaviour depends on several factors, including the connected cartridge. Some flash carts are not prepared for this unexpected scenario, and a bus conflict or worse behaviour can happen.

Table 4.1: OAM DMA address decoding scheme

DMA register value	Used bus	Asserted chip select signal
<code>0x00–0x7F</code>	external bus	external ROM (A15)
<code>0x80–0x9F</code>	video RAM bus	video RAM (MCS)
<code>0xA0–0xFF</code>	external bus	external RAM (CS)

Game Boy game cartridges

Chapter 8

MBC1 mapper chip

The majority of games for the original Game Boy use the MBC1 chip. MBC1 supports ROM sizes up to 16 Mbit (128 banks of 0x4000 bytes) and RAM sizes up to 256 Kbit (4 banks of 0x2000 bytes). The information in this section is based on my MBC1 research, Tauwasser's research notes [7], and Pan Docs [3].

8.1 MBC1 registers

These registers don't have any standard names and are usually referred to using their address ranges or purposes instead. This document uses names to clarify which register is meant when referring to one.

The MBC1 chip includes four registers that affect the behaviour of the chip. Of the cartridge bus address signals, only A13-A15 are connected to the MBC, so lower address bits don't matter when the CPU is accessing the MBC and all registers are effectively mapped to address ranges instead of single addresses. All registers are smaller than 8 bits, and unused bits are simply ignored during writes. The registers are not directly readable.

Register 8.1: 0x0000-0x1FFF - RAMG - MBC1 RAM gate register

U	U	U	U	W-0	W-0	W-0	W-0
				RAMG<3:0>			
bit 7	6	5	4	3	2	1	bit 0

bit 7-4 **Unimplemented:** Ignored during writes

bit 3-0 **RAMG<3:0>:** RAM gate register
0b1010= enable access to cartridge RAM
All other values disable access to cartridge RAM

The RAMG register is used to enable access to the cartridge SRAM if one exists on the cartridge circuit board. RAM access is disabled by default but can be enabled by writing to the 0x0000-0x1FFF address range a value with the bit pattern 0b1010 in the lower nibble. Upper bits don't matter, but any other bit pattern in the lower nibble disables access to RAM.

When RAM access is disabled, all writes to the external RAM area 0xA000-0xBFFF are ignored, and reads return undefined values. Pan Docs recommends disabling RAM when it's not being accessed to protect the contents [3].

We don't know the physical implementation of RAMG, but it's certainly possible that the 0b1010 bit pattern check is done at write time and the register actually consists of just a single bit.

Register 8.2: 0x2000–0x3FFF - BANK1 - MBC1 bank register 1

U	U	U	W-0	W-0	W-0	W-0	W-1
			BANK1 <4:0>				
bit 7	6	5	4	3	2	1	bit 0

bit 7-5 **Unimplemented:** Ignored during writes

bit 4-0 **BANK1<4:0>:** Bank register 1
 Never contains the value 0b00000.
 If 0b00000 is written, the resulting value will be 0b00001 instead.

The 5-bit BANK1 register is used as the lower 5 bits of the ROM bank number when the CPU accesses the 0x4000–0x7FFF memory area.

MBC1 doesn't allow the BANK1 register to contain zero (bit pattern 0b00000), so the initial value at reset is 0b00001 and attempting to write 0b00000 will write 0b00001 instead. This makes it impossible to read banks 0x00, 0x20, 0x40 and 0x60 from the 0x4000–0x7FFF memory area, because those bank numbers have 0b00000 in the lower bits. Due to the zero value adjustment, requesting any of these banks actually requests the next bank (e.g. 0x21 instead of 0x20).

Register 8.3: 0x4000–0x5FFF - BANK2 - MBC1 bank register 2

U	U	U	U	U	U	W-0	W-0
						BANK2 <1:0>	
bit 7	6	5	4	3	2	1	bit 0

bit 7-2 **Unimplemented:** Ignored during writes

bit 1-0 **BANK2<1:0>:** Bank register 2

The 2-bit BANK2 register can be used as the upper bits of the ROM bank number, or as the 2-bit RAM bank number. Unlike BANK1, BANK2 doesn't disallow zero, so all 2-bit values are possible.

Register 8.4: 0x6000–0x7FFF - MODE - MBC1 mode register

U	U	U	U	U	U	U	W-0
							MODE
bit 7	6	5	4	3	2	1	bit 0

bit 7-1 **Unimplemented:** Ignored during writes

bit 0 **MODE:** Mode register
 0b1 = BANK2 affects accesses to 0x0000–0x3FFF, 0x4000–0x7FFF, 0xA000–0xBFFF
 0b0 = BANK2 affects only accesses to 0x4000–0x7FFF

The MODE register determines how the BANK2 register value is used during memory accesses.

Most documentation, including Pan Docs [3], calls value 0b0 ROM banking mode, and value 0b1 RAM banking mode. This terminology reflects the common use cases, but "RAM banking" is slightly misleading because value 0b1 also affects ROM reads in multicart cartridges and cartridges that have a 8 or 16 Mbit ROM chip.

8.2 ROM in the 0x0000–0x7FFF area

In MBC1 cartridges, the A0-A13 cartridge bus signals are connected directly to the corresponding ROM pins, and the remaining ROM pins (A14-A20) are controlled by the MBC1. These remaining pins form the ROM bank number.

When the `0x0000–0x3FFF` address range is accessed, the effective bank number depends on the MODE register. In MODE `0b0` the bank number is always 0, but in MODE `0b1` it's formed by shifting the BANK2 register value left by 5 bits.

When the `0x4000–0x7FFF` address range is accessed, the effective bank number is always a combination of BANK1 and BANK2 register values.

If the cartridge ROM is smaller than 16 Mbit, there are less ROM address pins to connect to and therefore some bank number bits are ignored. For example, 4 Mbit ROMs only need a 5-bit bank number, so the BANK2 register value is always ignored because those bits are simply not connected to the ROM.

Table 8.1: Mapping of physical ROM address bits in MBC1 carts

Accessed address	ROM address bits		
	Bank number	Address within bank	
	20-19	18-14	13-0
<code>0x0000–0x3FFF</code> , MODE = <code>0b0</code>	<code>0b00</code>	<code>0b000000</code>	A<13:0>
<code>0x0000–0x3FFF</code> , MODE = <code>0b1</code>	BANK2	<code>0b000000</code>	A<13:0>
<code>0x4000–0x7FFF</code>	BANK2	BANK1	A<13:0>

ROM banking example 1

Let's assume we have previously written `0x12` to the BANK1 register and `0b01` to the BANK2 register. The effective bank number during ROM reads depends on which address range we read and on the value of the MODE register:

Value of the BANK1 register

`0b 10010`

Value of the BANK2 register

`0b 01`

Effective ROM bank number (reading `0x4000–0x7FFF`)

`0b 01 10010` (= 50 = `0x32`)

Effective ROM bank number (reading `0x0000–0x3FFF`, MODE = `0b0`)

`0b 00 00000` (= 0 = `0x00`)

Effective ROM bank number (reading `0x0000–0x3FFF`, MODE = `0b1`)

`0b 01 00000` (= 32 = `0x20`)

ROM banking example 2

Let's assume we have previously requested ROM bank number 68, MBC1 mode is `0b0`, and we are now reading a byte from `0x72A7`. The actual physical ROM address that will be read is going to be `0x1132A7` and is constructed in the following way:

Value of the BANK1 register `0b 00100`

Value of the BANK2 register `0b 10`

ROM bank number `0b 10 00100` (= 68 = `0x44`)

Address being read `0b 01 11 0010 1010 0111` (= `0x72A7`)

Actual physical ROM address `0b 1 0 001 00 11 0010 1010 0111` (= `0x1132A7`)

8.3 RAM in the `0xA000–0xBFFF` area

Some MBC1 carts include SRAM, which is mapped to the `0xA000–0xBFFF` area. If no RAM is present, or RAM is not enabled with the RAMG register, all reads return undefined values and writes have no effect.

On boards that have RAM, the A0-A12 cartridge bus signals are connected directly to the corresponding RAM pins, and pins A13-A14 are controlled by the MBC1. Most of the time the RAM size is 64 Kbit, which

corresponds to a single bank of 0x2000 bytes. With larger RAM sizes the BANK2 register value can be used for RAM banking to provide the two high address bits.

In MODE 0b0 the BANK2 register value is not used, so the first RAM bank is always mapped to the 0xA000–0xBFFF area. In MODE 0b1 the BANK2 register value is used as the bank number.

Table 8.2: Mapping of physical RAM address bits in MBC1 carts

Accessed address	RAM address bits	
	Bank number	Address within bank
	14-13	12-0
0xA000–0xBFFF, MODE = 0b0	0b00	A<12:0>
0xA000–0xBFFF, MODE = 0b1	BANK2	A<12:0>

RAM banking example 1

Let's assume we have previously written 0b10 to the BANK2 register, MODE is 0b1, RAMG is 0b1010 and we are now reading a byte from 0xB123. The actual physical RAM address that will be read is going to be 0x5123 and is constructed in the following way:

Value of the BANK2 register 0b 10

Address being read 0b 101 1 0001 0010 0011 (= 0xB123)

Actual physical RAM address 0b 10 1 0001 0010 0011 (= 0x5123)

8.4 MBC1 multicarts ("MBC1M")

MBC1 is also used in a couple of "multicart" cartridges, which include more than one game on the same cartridge. These cartridges use the same regular MBC1 chip, but the circuit board is wired a bit differently. This alternative wiring is sometimes called "MBC1M", but technically the mapper chip is the same. All known MBC1 multicarts use 8 Mbit ROMs, so there's no definitive wiring for other ROM sizes.

In MBC1 multicarts bit 4 of the BANK1 register is not physically connected to anything, so it's skipped. This means that the bank number is actually a 6-bit number. In all known MBC1 multicarts the games reserve 16 banks each, so BANK2 can actually be considered "game number", while BANK1 is the internal bank number within the selected game. At reset BANK2 is 0b00, and the "game" in this slot is actually a game selection menu. The menu code selects MODE 0b1 and writes the game number to BANK2 once the user selects a game.

From a ROM banking point of view, multicarts simply skip bit 4 of the BANK1 register, but otherwise the behaviour is the same. MODE 0b1 guarantees that all ROM accesses, including accesses to 0x0000–0x3FFF, use the BANK2 register value.

Table 8.3: Mapping of physical ROM address bits in MBC1 multicarts

Accessed address	ROM address bits		
	Bank number		Address within bank
	19-18	17-14	13-0
0x0000–0x3FFF, MODE = 0b0	0b00	0b0000	A<13:0>
0x0000–0x3FFF, MODE = 0b1	BANK2	0b0000	A<13:0>
0x4000–0x7FFF	BANK2	BANK1<3:0>	A<13:0>

ROM banking example 1

Let's assume we have previously requested "game number" 3 (= 0b11) and ROM bank number 29 (= 0x1D), MBC1 mode is 0b1, and we are now reading a byte from 0x6C15. The actual physical ROM address that will be read is going to be 0xF6C15 and is constructed in the following way:

Value of the BANK1 register 0b 1 1101

Value of the BANK2 register 0b 11

ROM bank number 0b 11 1101 (= 61 = 0x3D)

Address being read 0b 01 10 1100 0001 0101 (= 0x6C15)

Actual physical ROM address 0b 11 11 01 10 1100 0001 0101 (= 0xF6C15)

Detecting multicarts

MBC1 multicarts are not detectable by simply looking at the ROM header, because the ROM type value is just one of the normal MBC1 values. However, detection is possible by going through BANK2 values and looking at "bank 0" of each multicart game and doing some heuristics based on the header data. All the included games, including the game selection menu, have proper header data. One example of a good heuristic is logo data verification.

So, if you have a 8 Mbit cart with MBC1, first assume that it's a multicart and bank numbers are 6-bit values. Set BANK1 to zero and loop through the four possible BANK2 values while checking the data at 0x0104–0x0133. In other words, check logo data starting from physical ROM locations 0x00104, 0x40104, 0x80104, and 0xC0104. If proper logo data exists with most of the BANK2 values, the cart is most likely a multicart. Note that multicarts can just have two actual games, so one of the locations might not have the header data in place.

8.5 Dumping MBC1 carts

MBC1 cartridge dumping is fairly straightforward with the right hardware. The total number of banks is read from the header, and each bank is read one byte at a time. However, BANK1 register zero-adjustment and multicart cartridges need to be considered in ROM dumping code.

Banks 0x20, 0x40 and 0x60 can only be read from the 0x0000–0x3FFF memory area and only when MODE register value is 0b1. Using MODE 0b1 has no undesirable effects when doing ROM dumping, so using it at all times is recommended for simplicity.

Multicarts should be detected using the logo check described earlier, and if a multicart is detected, BANK1 should be considered a 4-bit register in the dumping code.

```

write_byte(0x6000, 0x01)
for bank in range(0, num_banks):
    write_byte(0x2000, bank)
    if is_multicart:
        write_byte(0x4000, bank >> 4)
        bank_start = 0x4000 if bank & 0x0f else 0x0000
    else:
        write_byte(0x4000, bank >> 5)
        bank_start = 0x4000 if bank & 0x1f else 0x0000
    for addr in range(bank_start, bank_start + 0x4000):
        buf += read_byte(addr)

```

Listing 1: Python pseudo-code for MBC1 ROM dumping

Chapter 9

MBC2 mapper chip

MBC2 supports ROM sizes up to 2 Mbit (16 banks of 0x4000 bytes) and includes an internal 512x4 bit RAM array, which is its unique feature. The information in this section is based on my MBC2 research, Tauwasser's research notes [8], and Pan Docs [3].

MBC1 is strictly more powerful than MBC2 because it supports more ROM and RAM. This raises a very important question: why does MBC2 exist? It's possible that Nintendo tried to integrate a small amount of RAM on the MBC chip for cost reasons, but it seems that this didn't work out very well since all later MBCs revert this design decision and use separate RAM chips.

9.1 MBC2 registers

These registers don't have any standard names and are usually referred to using one of their addresses or purposes instead. This document uses names to clarify which register is meant when referring to one.

The MBC2 chip includes two registers that affect the behaviour of the chip. The registers are mapped a bit differently compared to other MBCs. Both registers are accessible within 0x0000–0x3FFF, and within that range, the register is chosen based on the A8 address signal. In practice, this means that the registers are mapped to memory in an alternating pattern. For example, 0x0000, 0x2000 and 0x3000 are RAMG, and 0x0100, 0x2100 and 0x3100 are ROMB. Both registers are smaller than 8 bits, and unused bits are simply ignored during writes. The registers are not directly readable.

Register 9.1: 0x0000–0x3FFF when A8=0b0 - RAMG - MBC2 RAM gate register

U	U	U	U	W-0	W-0	W-0	W-0
				RAMG<3:0>			
bit 7	6	5	4	3	2	1	bit 0

bit 7-4 **Unimplemented:** Ignored during writes

bit 3-0 **RAMG<3:0>:** RAM gate register
0b1010= enable access to chip RAM
All other values disable access to chip RAM

The 4-bit MBC2 RAMG register works in a similar manner as MBC1 RAMG, so the upper bits don't matter and only the bit pattern 0b1010 enables access to RAM.

When RAM access is disabled, all writes to the external RAM area 0xA000–0xBFFF are ignored, and reads return undefined values. Pan Docs recommends disabling RAM when it's not being accessed to protect the contents [3].

We don't know the physical implementation of RAMG, but it's certainly possible that the 0b1010 bit pattern check is done at write time and the register actually consists of just a single bit.

Register 9.2: 0x0000–0x3FFF when A8=0b1 - ROMB - MBC2 ROM bank register

U	U	U	U	W-0	W-0	W-0	W-1
				ROMB<3:0>			
bit 7	6	5	4	3	2	1	bit 0

bit 7-4 **Unimplemented:** Ignored during writes

bit 3-0 **ROMB<3:0>:** ROM bank register
Never contains the value 0b0000.
If 0b0000 is written, the resulting value will be 0b0001 instead.

The 4-bit ROMB register is used as the ROM bank number when the CPU accesses the 0x4000–0x7FFF memory area.

Like MBC1 BANK1, the MBC2 ROMB register doesn't allow zero (bit pattern 0b0000) in the register, so any attempt to write 0b0000 writes 0b0001 instead.

9.2 ROM in the 0x0000–0x7FFF area

In MBC2 cartridges, the A0-A13 cartridge bus signals are connected directly to the corresponding ROM pins, and the remaining ROM pins (A14-A17) are controlled by the MBC2. These remaining pins form the ROM bank number.

When the 0x0000–0x3FFF address range is accessed, the effective bank number is always 0.

When the 0x4000–0x7FFF address range is accessed, the effective bank number is the current ROMB register value.

Table 9.1: Mapping of physical ROM address bits in MBC2 carts

Accessed address	ROM address bits	
	Bank number	Address within bank
	17-14	13-0
0x0000–0x3FFF	0b0000	A<13:0>
0x4000–0x7FFF	ROMB	A<13:0>

9.3 RAM in the 0xA000–0xBFFF area

All MBC2 carts include SRAM, because it is located directly inside the MBC2 chip. These cartridges never use a separate RAM chip, but battery backup circuitry and a battery are optional. If RAM is not enabled with the RAMG register, all reads return undefined values and writes have no effect.

MBC2 RAM is only 4-bit RAM, so the upper 4 bits of data do not physically exist in the chip. When writing to it, the upper 4 bits are ignored. When reading from it, the upper 4 data signals are not driven by the chip, so their content is undefined and should not be relied on.

MBC2 RAM consists of 512 addresses, so only A0-A8 matter when accessing the RAM region. There is no banking, and the 0xA000–0xBFFF area is larger than the RAM, so the addresses wrap around. For example, accessing 0xA000 is the same as accessing 0xA200, so it is possible to write to the former address and later read the written data using the latter address.

Table 9.2: Mapping of physical RAM address bits in MBC2 carts

Accessed address	RAM address bits
	8-0
0xA000–0xBFFF	A<8:0>

9.4 Dumping MBC2 carts

MBC2 cartridges are very simple to dump. The total number of banks is read from the header, and each bank is read one byte at a time. ROMB zero adjustment must be considered in the ROM dumping code, but this only means that bank 0 should be read from 0x0000–0x3FFF and not from 0x4000–0x7FFF like other banks.

```
for bank in range(0, num_banks):
    write_byte(0x2100, bank)
    bank_start = 0x4000 if bank > 0 else 0x0000
    for addr in range(bank_start, bank_start + 0x4000):
        buf += read_byte(addr)
```

Listing 2: Python pseudo-code for MBC2 ROM dumping

Chapter 10

MBC3 mapper chip

MBC3 supports ROM sizes up to 16 Mbit (128 banks of 0x4000 bytes), and RAM sizes up to 256 Kbit (4 banks of 0x2000 bytes). It also includes a real-time clock (RTC) that can be clocked with a quartz crystal on the cartridge even when the Game Boy is powered down. The information in this section is based on my MBC3 research, and Pan Docs [3].

Chapter 11

MBC30 mapper chip

MBC30 is a variant of MBC3 used by Japanese Pokemon Crystal to support a larger ROM chip and a larger RAM chip. Featurewise MBC30 is almost identical to MBC3, but supports ROM sizes up to 32 Mbit (256 banks of 0x4000 bytes), and RAM sizes up to 512 Kbit (8 banks of 0x2000 bytes). Information in this section is based on my MBC30 research.

The circuit board of Japanese Pokemon Crystal includes a 1 Mbit RAM chip, but MBC30 is limited to 512 Kbit RAM. One of the RAM address pins is unused, so half of the RAM is wasted and is inaccessible without modifications. So, the game only uses 512 Kbit and there is a mismatch between accessible and the physical amounts of RAM.

Chapter 12

MBC5 mapper chip

The majority of games for Game Boy Color use the MBC5 chip. MBC5 supports ROM sizes up to 64 Mbit (512 banks of 0x4000 bytes), and RAM sizes up to 1 Mbit (16 banks of 0x2000 bytes). The information in this section is based on my MBC5 research, and The Cycle-Accurate Game Boy Docs [1].

12.1 MBC5 registers

Register 12.1: 0x0000–0x1FFF - RAMG - MBC5 RAM gate register

W-0	W-0	W-0	W-0	W-0	W-0	W-0	W-0
RAMG<7:0>							
bit 7	6	5	4	3	2	1	bit 0

bit 7-0 **RAMG<7:0>**: RAM gate register
0b00001010= enable access to cartridge RAM
All other values disable access to cartridge RAM

The 8-bit MBC5 RAMG register works in a similar manner as MBC1 RAMG, but it is a full 8-bit register so upper bits matter when writing to it. Only 0b00001010 enables RAM access, and all other values (including 0b10001010 for example) disable access to RAM.

When RAM access is disabled, all writes to the external RAM area 0xA000–0xBFFF are ignored, and reads return undefined values. Pan Docs recommends disabling RAM when it's not being accessed to protect the contents [3].

We don't know the physical implementation of RAMG, but it's certainly possible that the 0b00001010 bit pattern check is done at write time and the register actually consists of just a single bit.

Register 12.2: 0x2000–0x2FFF - ROMB0 - MBC5 lower ROM bank register

W-0	W-0	W-0	W-0	W-0	W-0	W-0	W-1
ROMB0<7:0>							
bit 7	6	5	4	3	2	1	bit 0

bit 7-0 **ROMB0<7:0>**: Lower ROM bank register

The 8-bit ROMB0 register is used as the lower 8 bits of the ROM bank number when the CPU accesses the 0x4000–0x7FFF memory area.

Register 12.3: 0x3000–0x3FFF - ROMB1 - MBC5 upper ROM bank register

U	U	U	U	U	U	U	W-0
							ROMB1
bit 7	6	5	4	3	2	1	bit 0

bit 7-1 **Unimplemented:** Ignored during writes

bit 0 **ROMB1:** Upper ROM bank register

The 1-bit ROMB1 register is used as the most significant bit (bit 9) of the ROM bank number when the CPU accesses the 0x4000–0x7FFF memory area.

Register 12.4: 0x4000–0x5FFF - RAMB - MBC5 RAM bank register

U	U	U	U	W-0	W-0	W-0	W-0
				RAMB<3:0>			
bit 7	6	5	4	3	2	1	bit 0

bit 7-4 **Unimplemented:** Ignored during writes

bit 3-0 **RAMB<3:0>:** RAM bank register

The 4-bit RAMB register is used as the RAM bank number when the CPU accesses the 0xA000–0xBFFF memory area.

Chapter 13

MBC6 mapper chip

MBC6 supports ROM sizes up to 16 Mbit (256 banks of 0x2000 bytes), and RAM sizes up to 4 Mbit (128 banks of 0x1000 bytes). The information in this section is based on my MBC6 research.

MBC7

TODO.

Chapter 15

HuC-1 mapper chip

HuC-1 supports ROM sizes up to 8 Mbit (64 banks of 0x4000 bytes), and RAM sizes up to 256 Kbit (4 banks of 0x2000 bytes). It also includes a sensor and a LED for infrared communication. The information in this section is based on my HuC-1 research.

Chapter 16

HuC-3 mapper chip

HuC-3 supports ROM sizes up to 16 Mbit (128 banks of 0x4000 bytes), and RAM sizes up to 1 Mbit (16 banks of 0x2000 bytes). Like HuC-1, it includes support for infrared communication, but also includes a real-time-clock (RTC) and output pins used to control a piezoelectric buzzer. The information in this section is based on my HuC-3 research.
